

Only 20% of Netflix India uploads generated nearly 90% of total channel views.

This is the story of what the data underneath revealed.

NOW STREAMING

Codebasics Virtual Internship - Netflix India YouTube Analysis

Most YouTube reporting focuses on views, likes, and upload counts.

But those numbers do not explain:

- why some videos dominate,
- which formats consistently perform better,
- or whether performance is evenly distributed across uploads.

The analysis became less about reporting and more about identifying scalable patterns.

So I analyzed Netflix India's YouTube performance across:

- Content Format
- Video Duration
- Title Length
- Metadata Usage
- Publishing Windows
- Top-Performing Patterns

The goal was identifying which observable factors were associated with stronger reach performance.

Long-Form Content Dominated Total Reach.

The dashboard showed:

- Long-form $\approx 91.69\%$ of total views
- Shorts $\approx 8.31\%$

Within this dataset, long-form uploads generated the overwhelming majority of aggregate audience reach.

Performance Was Highly Concentrated

90%

Top 20% Contribution

Approximately 20% of uploads generated nearly 90% of total channel views.

Overall channel performance was heavily concentrated among a relatively small subset of videos.

Performance consistency depended on a limited number of breakout-performing uploads.

The Best Performing Videos Weren't The Shortest Ones

The 1-5 minute duration bucket generated the highest average views among displayed categories.

Mid-length uploads generated stronger average view performance within this dataset.

More Tags Didn't Mean More Reach

1-5 Tags

Highest

10+ Tags

Medium

6-10 Tags

Lower

Videos with moderate tag counts outperformed heavily tagged uploads in average views.

Increasing metadata quantity alone did not correspond with stronger average performance.

Longer Titles Outperformed Short Titles

Long-title uploads generated higher average views than short-title videos.

This does not prove causation — only measurable association within the dataset.

Short-title structures did not consistently outperform more detailed title formats.

Publishing Timing Was Associated With Performance Variation

The publishing heatmap showed Morning and Afternoon upload windows consistently generating stronger average performance than Late Night periods.

Upload timing appeared associated with measurable differences in average reach performance.

The Real Story Wasn't "More Uploads = More Success"

The data suggested channel performance depended heavily on:

- concentrated breakout-performing uploads,
- repeatable high-performing formats,
- recurring franchise and show-based content

Performance appeared concentrated around repeatable high-performing structures rather than upload volume alone.

The Analysis Suggested Five Strategic Priorities

1. Prioritize long-form and mid-length formats.
2. Use publishing timing to amplify reach.
3. Focus on repeatable high-performing content patterns.
4. Keep metadata optimized, not excessive.
5. Continue analyzing recurring franchise performance.

The strongest value came from evidence-backed interpretation rather than dashboard complexity.

This Project Changed How I Think About Analytics

This project helped me think less like a dashboard builder and more like an analyst solving a content strategy problem.

Tools Used
Power BI • DAX • KPI Modeling

Focus Areas
Business Intelligence • Validation • Analytics Storytelling

Recruiters, hiring managers, and peers — I'd love your feedback on the analysis.
